SWEETTOOTH INC.

Here's a link to my completed module:

https://tryhackme.com/room/sweettoothinc?utm_campaign=social_share&utm_medium=social&utm_content=share-completed-room&utm_source=copy&sharerId=64fca550f47415574dbafdb9

1.1 Introduction

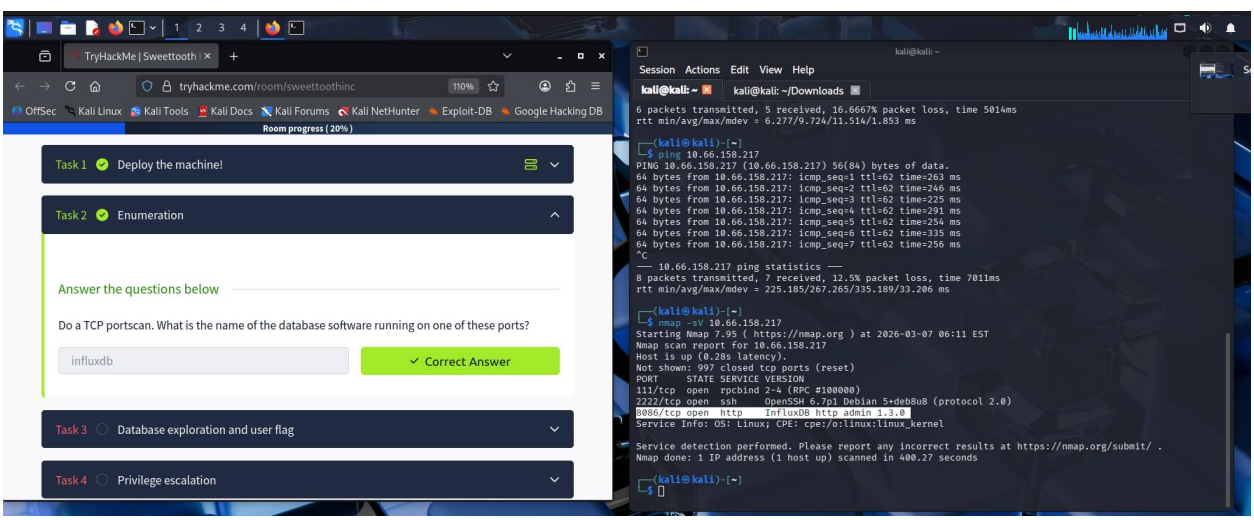
The Sweettooth Inc. room on TryHackMe provides a hands-on simulation of a multi-stage cyberattack within a containerized architecture. This challenge is designed to test a student's ability to transition from external enumeration to full system compromise by exploiting common misconfigurations in database management and container security. I can expect to learn the nuances of interacting with SQL databases to extract credentials, navigating Linux filesystems under restricted shell conditions, and identifying the specific vectors required for privilege escalation. The room culminates in a "container escape" scenario, teaching the critical relationship between a Dockerized instance and its underlying host.

1.2 Enumeration

Do a TCP portscan. What is the name of the database software running on one of these ports?

I ran the command: nmap -sV 10.66.158.217

Ans: InfluxDB

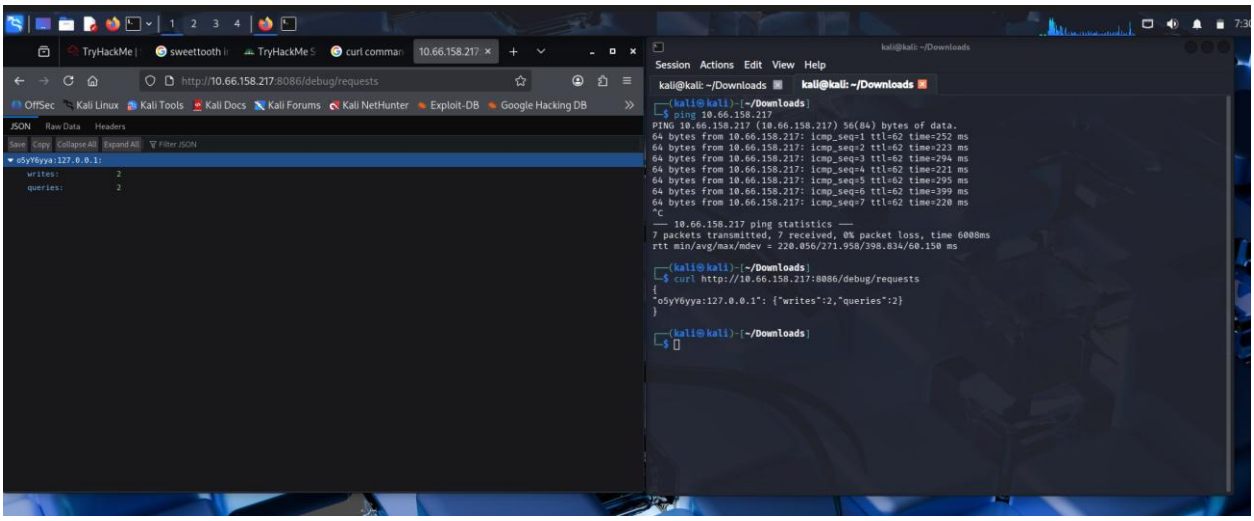


1.3 Database Exploration and User Flag

What is the database user you find?

I first searched for vulnerabilities of InfluxDB http admin 1.3.0 and found the Authentication bypass then searched http://10.66.158.217:8086/debug/requests to find a username

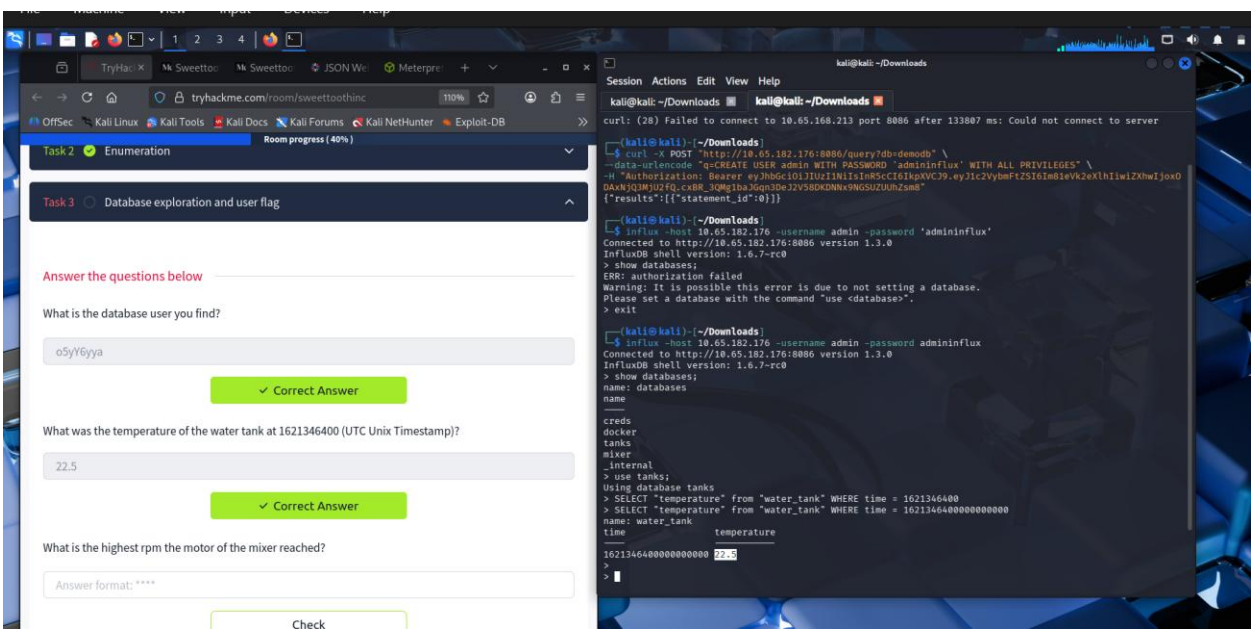
Ans: o5yY6yya



What was the temperature of the water tank at 1621346400 (UTC Unix Timestamp)?

I was able to create a user admin with all privileges then viewed the databases to find tanks databases then viewed the temp.

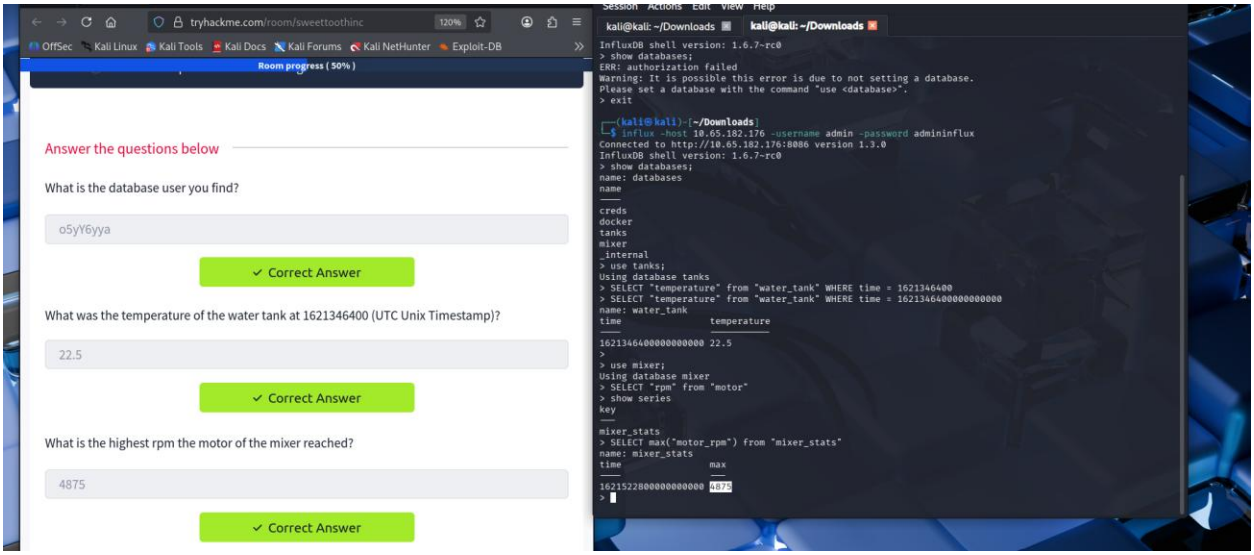
Ans: 22.5



What is the highest rpm the motor of the mixer reached?

I used the command: SELECT max("motor_rpm") from "mixer_stats"

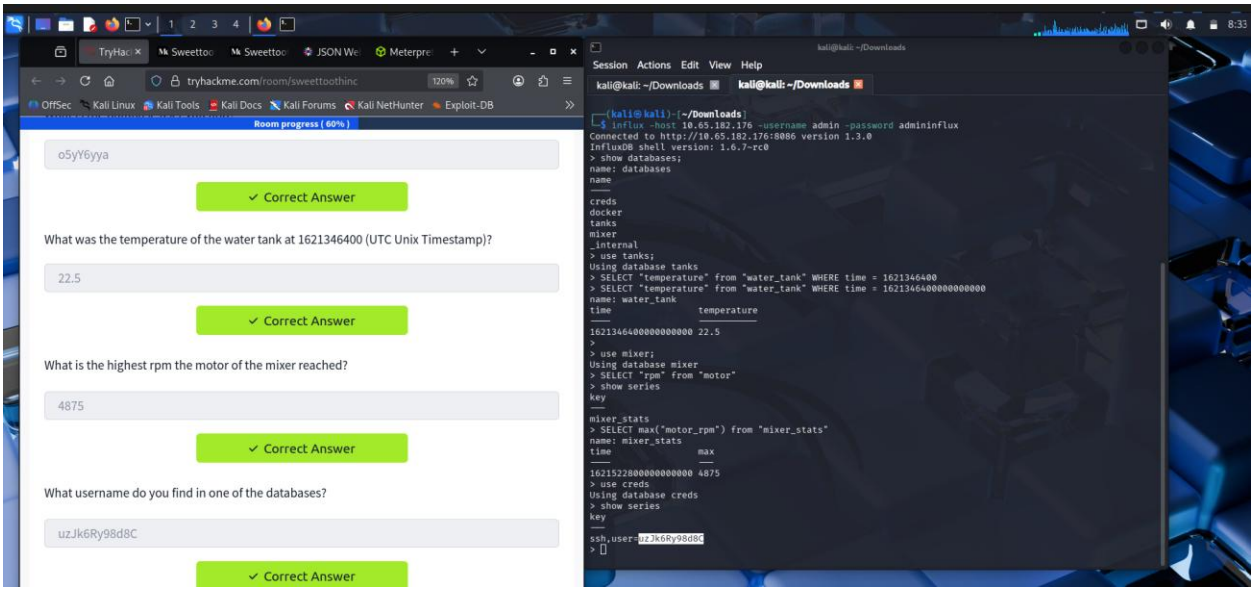
Ans: 4875



What username do you find in one of the databases?

I used the command show series

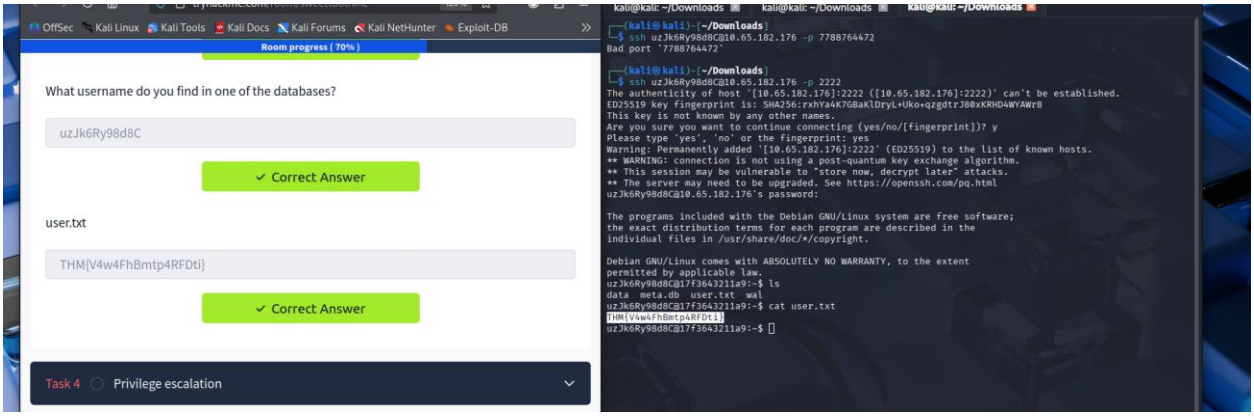
Ans: uzJk6Ry98d8C



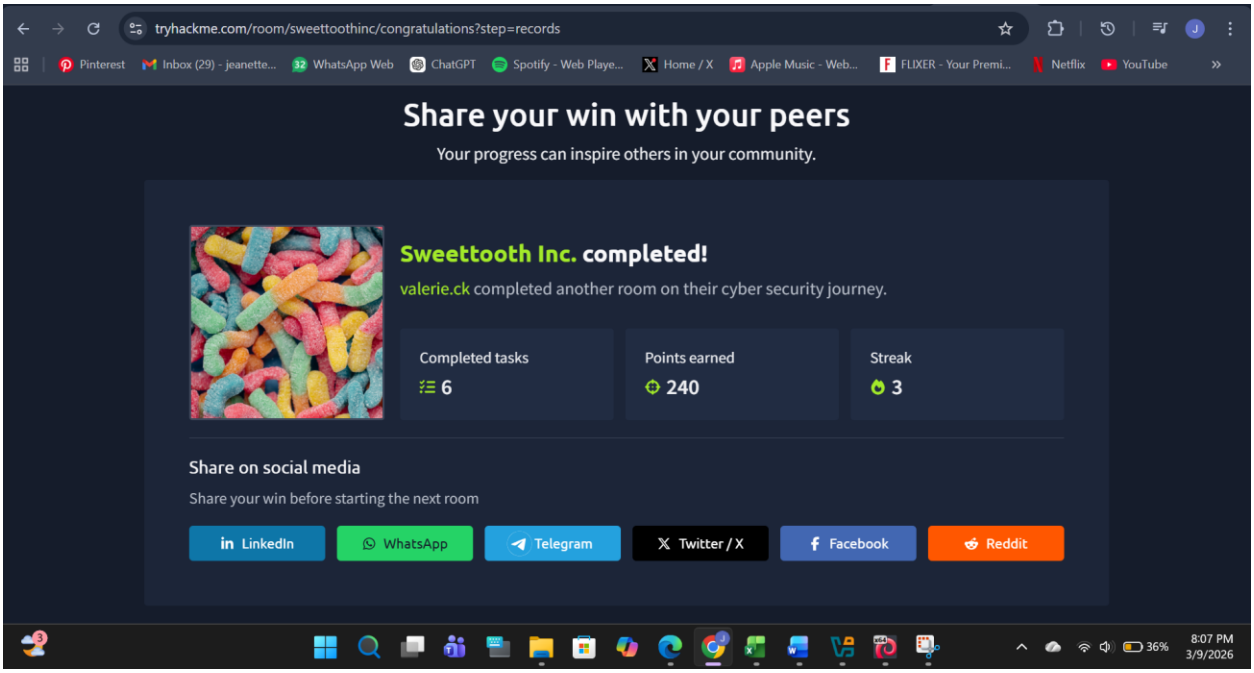
user.txt

I used ssh using the credentials found in the database, then found the txt as seen below

Ans: THM{V4w4FhBmtp4RFDti}



I was thus able to complete this room as seen below:



1.4 Conclusion

Completing the Sweettooth Inc. challenge solidified a practical understanding of the attack chain in a modern infrastructure environment. Through this room, I have successfully understood Identifying and interacting with ports to gain initial entry, utilizing SQL queries to pivot from database access to system-level user credentials. This exercise underscores the vital importance of securing internal database communications and properly configuring container permissions to prevent unauthorized host access.
